Can the company pay you back?

Creditworthiness is about meeting obligations on time, including when the business disappoints.

A practical guide to company survival, bond recovery, default risk and credit spreads. Learn the method, work through Apple, then apply it to AI infrastructure financing.

The question	The evidence	The investor decision
Will it pay?	Cash generation, liquidity, debt maturities and stress scenarios.	Choose an issuer and a maturity you can defend.
What if it does not?	Collateral, creditor priority, guarantees and enterprise value in distress.	Estimate loss severity for the exact instrument.
Am I paid enough?	Yield, benchmark spread, duration, liquidity and embedded options.	Compare compensation against expected loss and uncertainty.

Three ideas to carry through the report

1. A profitable company can run out of cash. A low-margin company can survive if its cash flows and funding are resilient.
2. A strong company can issue a risky long-duration bond. Bond price losses do not require default.
3. A wide moat or attractive stock valuation is not a promise that a particular bond is safe.

Scope: completed educational analysis, not a personalized recommendation, a rating-agency opinion, or a live bond-price service. Research checked 5 November 2026. Company comparison uses explicitly dated FY2025 statements, not the latest available TTM. Historical data and scenarios are kept separate.

Navigation: Use the PDF bookmarks or web contents for navigation. Sources [1-18] are linked in the register.

How credit analysis is built

There is no single universal creditworthiness formula.

Layer	Ask this	Evidence that changes the answer
Business resilience	Will customers keep paying through a downturn?	Revenue concentration; switching costs; pricing power; cyclicality; regulation.
Cash conversion	Does accounting profit become spendable cash?	Operating cash flow; receivables; inventories; supplier terms; recurring vs one-off effects.
Debt burden	How much has already been promised?	Borrowings; leases; guarantees; pensions; purchase commitments; debt at subsidiaries.
Liquidity and time	Can the next payment be made without a friendly market?	Unrestricted cash; committed facilities; covenant headroom; maturity calendar.
Financial policy	Who receives surplus cash?	Buybacks; dividends; acquisitions; willingness to preserve ratings or deleverage.
Instrument protection	Where does this bond stand in a failure?	Issuer entity; guarantors; collateral; seniority; covenants; governing law.

Analysts combine historical ratios with forecasts and judgment. Agency methods differ by sector and adjust accounting data differently. A bank, a property company and a software issuer cannot be ranked fairly using one unadjusted debt/EBITDA threshold.

Do not invent an agency grade. Record the actual agency, issuer or instrument, publication date, outlook and watch status. A rating outlook is not an additional notch. A rating is an opinion, not insurance.

Basis: independent teaching framework; rating-process distinction supported by Morningstar DBRS [5]. Credit ratings are forward-looking committee opinions, not mechanical scores.

The six calculations worth learning

Ratios are questions to investigate, not pass/fail rules.

Metric / formula	What it tells you	Main trap
Net debt = borrowings - eligible cash	Debt after a realistic liquidity offset.	Restricted cash, overseas taxes and securities haircuts matter. State whether leases are included.
Debt / EBITDA	Debt relative to operating earnings before D&A.	Adjusted EBITDA can exclude recurring costs; EBITDA is not cash available for principal.
EBIT / gross interest expense	Operating earnings buffer over financing expense.	Do not divide by net interest income. Capitalized interest and leases complicate coverage.
CFO - cash capex	Simple cash left after investment in fixed assets.	Not standardized FCF. Lease principal, acquisitions and shareholder payouts may be additional uses.
CFO / debt	Annual cash generation relative to borrowings.	Working-capital timing and one-off taxes can distort a single year.
12-month sources / uses	Near-term funding buffer under a specified scenario.	CFO already includes some uses, such as cash interest under US GAAP. Avoid double counting.

Build the bridge: cash from operations minus capex minus dividends minus buybacks minus acquisitions minus debt principal, plus new funding and asset sales. Track starting and ending cash separately.

For a simple liquidity forecast using CFO, do not subtract the same cash interest or working-capital outflow a second time. If starting from EBITDA instead, explicitly deduct interest, taxes, working-capital needs and capex.

Definitions here are classroom definitions, not agency-adjusted measures. There are no universal healthy cutoffs. Use consistent periods, currency, accounting basis and peer business models.

Default risk: probability is not certainty

Expected loss combines the chance of default with the loss if default occurs.

Expected loss = probability of default (PD) x loss given default (LGD) x exposure. If recovery is 40% of face value, LGD is 60%. For a $1,000 claim and a one-year PD of 2%, expected credit loss is $12. This is an average across uncertain outcomes, not a guaranteed $12 deduction.

One-year PD	20% recovery	40% recovery	60% recovery
1%	$8	$6	$4
2%	$16	$12	$8
5%	$40	$30	$20
10%	$80	$60	$40

Illustrative sensitivity table. Exposure $1,000; expected loss = PD x (1 - recovery) x $1,000. No issuer estimate or historical default-rate forecast. Recoveries ignore discounting and expenses here.

Time matters. With a constant independent annual default probability of 2%, five-year cumulative default probability is 1 - 0.98^5 = 9.61%, not exactly 10%. Real conditional probabilities change with the economic cycle and the company.

A rating-based historical default rate, a model estimate and a market-implied probability are different objects. Historical averages depend on rating category, cohort, horizon and default definition. A market-implied probability embeds risk pricing and should not be presented as the actual chance of bankruptcy.

What counts as default? Missed payments, bankruptcy and some distressed exchanges can qualify, depending on the agency or contract. A covenant breach can cause a funding problem without being identical to a missed coupon.

Sources: corporate default basics [1]; rating opinions [5]. All numerical scenarios and formulas on this page are independently constructed teaching examples.

Recovery: who gets paid first?

The value left for your claim matters more than the original asset price.

Recovery is the value received after default relative to the claim or other stated denominator. It may arrive as cash, new debt, equity or a mix, often after delay. A trading price soon after default and ultimate recovery are not the same measurement.

Illustrative waterfall	Claim	Cash paid	Recovery
Net distributable value after costs	$60m	Available pool	Not book value
Secured creditors	$30m	$30m	100%
Senior unsecured creditors	$50m	$30m	60%
Subordinated creditors	$20m	$0	0%
Common equity	Residual	$0	0%

Stress the asset value. If the distributable pool falls to $40m, the same senior unsecured class receives $10m / $50m = 20%. If it rises to $80m, that class receives 100%. A bond label alone cannot determine recovery.

This simplified example assumes secured claims are covered by collateral, the remaining priority rules are as shown, and there are no competing administrative, employee, tax or other priority claims. Real insolvency outcomes depend on law, collateral, guarantees and the specific corporate structure.

Structural subordination: a parent-company bond may have access only to the residual value of a subsidiary after that subsidiary pays its own creditors. Consolidated cash does not necessarily belong to the bond issuer.

Illustration, not a predicted recovery or legal advice. General creditor-priority concepts: SEC Investor.gov [1]. For an actual bond, read the indenture and guarantee/security documents; do not use this stylized ordering as a legal opinion.

Credit spread: separate the two prices

A bond yield can rise because Treasury yields rise, spreads widen, or both.

Simple benchmark spread = bond yield - comparable benchmark yield. One percentage point equals 100 basis points (bp). A 6.50% yield minus a 4.90% benchmark gives 1.60%, or 160bp. These rounded numbers are illustrative.

Measure	Use	Do not confuse it with
Coupon	Contractual interest as a percentage of face value.	Yield earned at today's purchase price.
Yield to maturity	Discount rate equating price to promised cash flows under stated conventions.	A guaranteed realized return if default, early sale or reinvestment differs.
Treasury / G-spread	Yield difference to a specified Treasury or interpolated government curve.	An option-adjusted spread or a same-day par-curve observation.
Z-spread	Constant spread added to spot rates to value promised cash flows.	A direct standalone probability of default.
Option-adjusted spread	Model-based spread after accounting for embedded options.	The raw spread of a callable bond.

Spread compensation reflects expected default losses, uncertainty around them, liquidity, risk appetite, supply-demand and bond-specific features. Tax and benchmark conventions can matter. Comparing a 30-year callable bond with a five-year noncallable bond by raw spread alone is misleading.

Useful shortcut, dangerous forecast: spread / LGD is a rough risk-neutral hazard-rate approximation under restrictive assumptions. At 160bp and 60% LGD, it gives about 2.67% per year. It is not a reliable physical default forecast and not a conclusion about Meta.

Sources: CFA Institute yield/spread concepts [6]. Numerical examples are independent teaching calculations; no live pricing or OAS estimates are supplied.

A bond can lose money without default

Longer duration magnifies sensitivity to both interest rates and spreads.

First-order price change (%) is approximately -duration x yield change in percentage points. For a credit bond, use rate duration for benchmark changes and spread duration for spread changes. Duration is not the same as maturity.

Illustrative shock	3-year duration	7-year duration	15-year duration
Yield +0.50 percentage point	-1.5%	-3.5%	-7.5%
Yield +1.00 percentage point	-3.0%	-7.0%	-15.0%
Yield -0.50 percentage point	+1.5%	+3.5%	+7.5%

Hypothetical modified durations; no actual security. Approximation excludes convexity, coupon carry, default, accrued interest and transaction costs. Large moves require full repricing; callable bonds may behave differently.

Offsetting forces example: benchmark yield falls 50bp while credit spread widens 100bp. If rate duration and spread duration are both 7, approximate price change is +3.5% - 7.0% = -3.5%, before carry and convexity.

Holding a solvent bond to maturity can avoid realizing an interim market-price decline, but it does not remove default risk, inflation, opportunity cost or the risk that you need cash before maturity. A bond fund has a portfolio and no single promise to repay your original purchase price on a specified date.

Refinancing channel: a company with fixed-rate debt is not immediately paying more on every bond when yields rise. The higher cost reaches floating-rate debt, new borrowing and maturities that must be refinanced. This is why the maturity ladder matters.

Sources: yield and option considerations [6]; SEC bond basics [1]. All calculations are illustrative and independently constructed.

Read Morningstar beside the 10-K

Use research to frame questions and filings to verify the numbers.

Morningstar lens	10-K evidence to inspect	Your credit question
Business / moat	Item 1: business; segments; customers.	How durable is demand and pricing power?
Risk and uncertainty	Item 1A: risk factors; subsequent updates.	Which shock could damage cash flow or financing?
Financial strength	Item 7 liquidity discussion; Item 8 cash flows and balance sheet.	Can it fund operations and obligations under stress?
Capital allocation	Dividends, repurchases, acquisitions and debt notes.	Will management protect creditors or spend the buffer?
Stock stars / fair value	Stock price and valuation assumptions.	This answers an equity valuation question, not bond safety.

Practical Apple workflow

1. Open the requested Morningstar AAPL Financials page. Select annual rather than quarterly or TTM, confirm USD units, and note the fiscal end date.
2. Compare cash-flow, balance-sheet and income-statement numbers with the same Apple filing.
3. Read liquidity, debt, leases and commitments notes. Add the latest 10-Q/8-K events before making a current decision.
4. Read the exact bond prospectus and indenture. A stock page is not a bond term sheet.

Morningstar equity stars concern valuation relative to estimated fair value and uncertainty. An economic moat concerns durable competitive advantage. Morningstar DBRS credit ratings are a separate credit-opinion process. Do not convert stars or moat labels into default probabilities.

Sources [2-5,14]. The live AAPL Financials interface and subscriber-only analyst report were not authenticated or reproduced. This is an original teaching workflow, not a claim to quote Apple's current Morningstar rating or proprietary research.

Apple: follow the cash, not just profit

FY2025 operating income grew, while cash after capex fell.

USD billions	FY2024	FY2025	Read it this way
Revenue	391.035	416.161	Sales are not cash receipts.
Operating income	123.216	133.050	Operating profitability increased.
Operating cash flow	118.254	111.482	Cash conversion moved differently.
Cash PP&E; purchases	9.447	12.715	Investment consumed more cash.
CFO minus cash capex	108.807	98.767	Before financing and distributions.
Borrowings	106.629	98.657	Not total liabilities.

Calculate it yourself: 111.482 - 12.715 = $98.767bn. Cash capex consumed 11.41% of CFO. CFO / borrowings = 1.13x. These are unadjusted classroom ratios, not an agency score.

At 27 September 2025, cash and equivalents were $35.934bn. Adding current marketable securities gives $54.697bn; adding noncurrent securities gives $132.420bn. Borrowings were $98.657bn, including $7.979bn commercial paper and $12.350bn current term debt.

Interpretation: broad liquid investments exceeded borrowings by $33.763bn, but calling all securities immediate cash would overstate precision. Test availability, maturity, market risk and operating cash needs. The strong cash-generation profile does not establish a numerical default probability or make every Apple bond attractive.

Sources: Apple FY2025 release with FY2024 comparatives [8]; annual filing for reading practice [14]. This intentionally teaches a fixed historical period. It is not Apple's latest financial position as of November 2026. Ratios calculated from displayed unrounded source inputs.

Apple: reconcile the denominator

Buybacks use cash; they are not a debt balance.

USD billions / ratio	Calculation	Result
Borrowings, carrying amount	7.979 CP + 12.350 current term + 78.328 noncurrent term	98.657
Cash-only net debt	98.657 - 35.934	62.723
Simple FCF / borrowings	98.767 / 98.657	1.001x
Operating income	Gross profit less operating expenses	133.050
Operating income + D&A proxy	133.050 + 11.698	144.748
Debt / proxy above	98.657 / 144.748	0.682x

EBITDA caution. The $133.050bn figure is operating income, not EBITDA. Adding disclosed depreciation and amortization produces a defined $144.748bn proxy; this is not a company-reported or agency-adjusted EBITDA measure.

Interest coverage is not calculated. A separately verified gross annual interest expense input is not available in this report. The $0.129bn sensitivity to a 100bp rate increase in Item 7A is an incremental hypothetical impact, not the interest expense denominator. No coverage ratio is inferred from it.

Priority correction. Debt claims generally rank ahead of common equity in insolvency. The bond’s entity, collateral and governing law determine its position among creditors; consolidated accounting labels alone do not establish recovery.

Source: Apple FY2025 Form 10-K [14], statements pp.29-33, Note 9 pp.43-44 and Item 7A p.27. Debt excludes lease liabilities; net debt here deducts cash and equivalents only. Share repurchases are excluded from the debt denominator. General priority: [1].

Apple: maturities and a cash stress test

A maturity calendar turns a balance-sheet number into dated cash needs.

FY maturity bucket	2026	2027	2028	2029	2030	Later
Term principal, USD bn	12.393	10.078	9.300	5.235	4.972	49.303

As of 27 September 2025; term-note principal totals $91.281bn. Excludes commercial paper and leases. Principal differs from carrying value; do not mix these measures. Source [14], Note 9 p.44. Not a current November 2026 maturity schedule.

Illustrative one-year case, USD bn	Base	CFO -25%	CFO -50%
Starting cash and equivalents	35.934	35.934	35.934
Annual CFO assumption	111.482	83.612	55.741
Cash capex assumption	(12.715)	(12.715)	(12.715)
2026 term principal + CP assumed repaid	(20.372)	(20.372)	(20.372)
Cash left before other uses	114.329	86.459	58.588

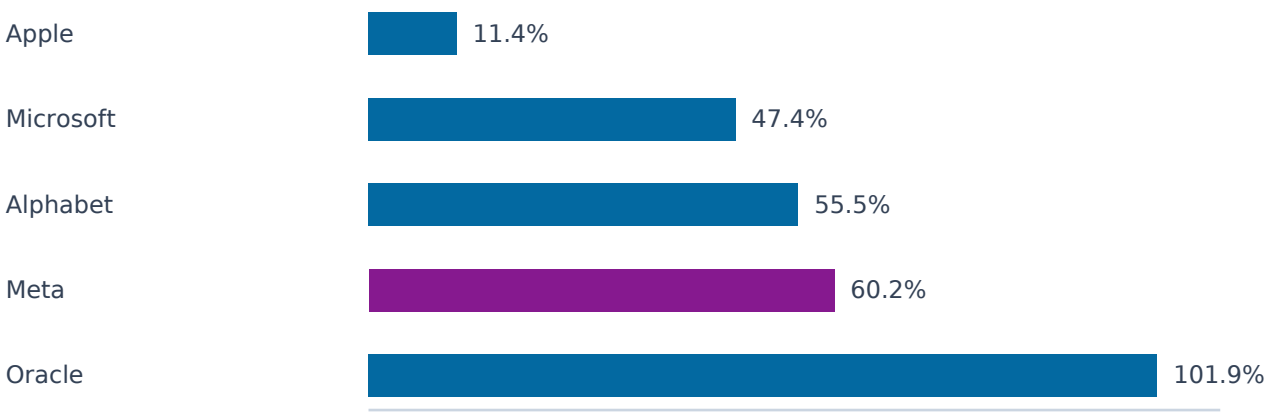

How to read it: this is a transparent cash bridge, not a solvency forecast. It assumes no new borrowing, no securities sales, unchanged cash capex, and repayment of the $7.979bn CP balance alongside 2026 note principal. CFO already includes operating cash uses such as interest under US GAAP.

The ending amounts exclude dividends, buybacks, acquisitions, financing-lease principal and any new extraordinary obligations. They do not establish that these cash balances would actually be available. Stress specific business drivers, working capital and minimum operating liquidity before making a real decision.

Classroom sensitivity based on historical [14] inputs. Calculations use full precision; the 25% CFO amount is displayed rounded. No independently estimated default probability, rating or forecast is implied.

Peer comparison: investment absorbs cash

Capex intensity is more revealing than a ranking of revenue alone.

Cash capex / operating cash flow, FY2025. A bar above 100% means this cash investment measure exceeded operating cash generated that year. Zero-based scale; exact inputs below. Not a credit rating.

USD bn / FY end	CFO	Cash capex	Difference	Borrowings
Apple 2025-09-27	111.482	12.715	98.767	98.657
Microsoft 2025-06-30	136.162	64.551	71.611	43.151
Alphabet 2025-12-31	164.713	91.447	73.266	48.543
Meta 2025-12-31	115.800	69.691	46.109	58.744
Oracle 2025-05-31	20.821	21.215	-0.394	92.568

Oracle is the useful contrast. FY2025 cash capex of $21.215bn slightly exceeded CFO of $20.821bn. That signals a need for cash reserves or external funding before additional uses; it does not by itself prove imminent default.

Cash capex excludes noncash lease additions. Meta also deducted $2.524bn of finance-lease principal in its own FCF, producing $43.585bn rather than the $46.109bn simple difference here. Borrowings exclude leases. Different fiscal ends and business models limit direct ranking.

Sources: issuer statements [8-12]. These are five issuers, not the entire AI supply chain. No forecasts, latest TTM figures, current ratings or unsupported R&D rankings are mixed into this table.

Five-issuer cash-flow ratio comparison

A cash-flow comparison is useful only when definitions and missing inputs remain visible.

Issuer / FY end	Operating margin	CFO / debt	CFO-capex / debt	Capex / CFO
Apple 2025-09-27	31.97%	1.130x	1.001x	11.41%
Microsoft 2025-06-30	45.62%	3.155x	1.660x	47.41%
Alphabet 2025-12-31	32.03%	3.393x	1.509x	55.52%
Meta 2025-12-31	41.44%	1.971x	0.785x	60.18%
Oracle 2025-05-31	30.80%	0.225x	-0.004x	101.89%

Definitions: operating margin = operating income / revenue. Debt = balance-sheet carrying borrowings including current maturities and commercial paper, excluding leases. CFO-capex is the simple measure on the prior page, not a uniform agency FCF definition.

Interpretation: a larger annual cash-flow/debt ratio gives more observed cash generation relative to borrowings, but it ignores the maturity distribution and future deterioration. Negative CFO-capex/debt indicates cash investment exceeded operating cash generation; it is not a negative debt balance.

No overall credit score or rating is assigned. Interest coverage, lease-adjusted leverage and peer maturity ladders are not reported because those inputs have not been reconciled consistently for this comparison. The completed table covers the five named issuers only, not every company in the original AI universe.

Source inputs and fiscal dates [8-12]. Oracle operating income is $17.678bn and revenue $57.399bn, giving a 30.80% operating margin. Annual fiscal periods differ; do not treat this as a synchronized quarter-end ranking. All ratios are this report’s calculations, not agency measures.

AI infrastructure: find the real obligor

Off-balance-sheet borrowing can still create economic exposure for the sponsor.

Funding route	Who borrows?	What to examine
Corporate bonds	Operating company or parent.	Use of proceeds, maturity, new leverage and cash-flow coverage.
Leases / capacity contracts	Owner or project vehicle; user promises future payments.	Cancellation terms, minimum payments, commencement timing and guarantees.
Project / private credit	SPV with pledged project assets and contracts.	Customer concentration, construction risk, collateral obsolescence and lender priority.
Equity or joint venture	Shareholders supply risk-bearing capital.	Dilution, control, capital calls and whether debt has sponsor recourse.

BIS Bulletin 140, published 27 October 2026, describes growing debt funding and complex vehicles for AI infrastructure. Commitments by large firms can support vehicle credit quality, and banks may be exposed both to vehicles and to investors in their debt. Its observed Treasury and investment-grade spillovers on AI-financing news days were small and short-lived; that is not proof of no future risk. [7]

Stress the chain: weaker AI demand -> lower utilization -> less project cash -> pressure on fixed contractual payments -> refinancing or collateral-sale risk. A technologically successful sector can still contain overleveraged borrowers.

NVIDIA illustrates why models differ: FY2025, ended 26 January 2025, generated $64.089bn CFO versus $3.236bn purchases of PP&E; and intangibles. Its fabless design model is not comparable with a data-center owner, and the period largely covers calendar 2024. Low own capex does not eliminate customer concentration or demand risk. [13]

R&D is an expense category; capex is investment in long-lived assets; acquisitions and lease commitments are different again. None is a clean, consistently disclosed total for AI spending. Do not add them blindly or call all infrastructure investment AI-only.

Read a financing headline precisely

Amount, rate, spread and use of proceeds answer different questions.

Documented pricing	What was priced	Correct interpretation
Microsoft 29 October 2026	$25bn total notes: $23bn fixed + $2bn floating.	The supplied $23bn figure describes the fixed-rate subset, not total issuance.
Oracle 2 November 2026	$10bn notes and a separate $10bn equity offering.	A $20bn combined financing headline is not $20bn of debt.
Meta 3 November 2026	$15bn across five senior-note tranches.	Pricing and expected settlement are not proof of completed settlement.

Meta maturity	Amount ($bn)	Coupon (%)	Issue YTM (%)	Spread (bp)
2031	3.25	5.850	5.850	110
2033	3.25	6.250	6.289	145
2036	4.00	6.550	6.552	160
2046	1.75	7.350	7.359	200
2056	2.75	7.500	7.531	220

Worked decomposition: the 2036 Meta tranche issue yield of 6.552% equals its 4.952% Treasury benchmark plus 160bp. Its coupon was 6.550%. The spread belongs to that benchmark at pricing, not to a Treasury par yield observed the next day.

Do not label all corporate proceeds AI-only when the documents state general corporate purposes. A longer tranche's higher yield can reflect duration and term compensation as well as credit concerns; it does not mean that five different bonds imply five simple issuer default forecasts.

Sources [15-18]. Meta filing text was rechecked via the StreetInsider reproduction [18]; direct SEC access was unavailable during final audit. Terms are historical issue-date terms, not current executable quotes. Meta expected settlement 5 November; completion not independently checked. Supplied 4 November Treasury curve and TBAC interpretation were not independently verified and are excluded.

Your repeatable survival checklist

Finish with a dated, conditional judgment, not a single reassuring ratio.

Check	Record before deciding
Identity and time	Exact legal issuer, guarantors, bond identifier, currency, financial period and pricing timestamp.
Cash engine	Three-year CFO history; working-capital drivers; capex split; leases; recurring vs one-off items.
Funding calendar	Cash available today; committed facilities; debt due in each year; covenant headroom.
Downside case	Revenue/margin shock; cash conversion; refinancing rate; capex flexibility; cash after unavoidable payments.
Recovery case	Priority, collateral value after costs, competing claims, guarantee coverage and recovery delay.
Price of risk	Comparable maturity and currency; spread definition; duration; call schedule; bid-ask and trading size.
Decision and trigger	Why compensation is sufficient or not; what new fact changes the conclusion; next filing date.

Example decision language: "On the stated historical data, the issuer has substantial cash-generation capacity. I would still need updated liquidity, its maturity schedule and this bond's spread and protections before judging whether the bond offers adequate compensation."

Red flags to investigate: persistent CFO weakness despite profit growth; rising receivables; large near-term maturities; aggressive EBITDA adjustments; expensive refinancing; weak covenant headroom; dividends funded with debt; guarantees or purchase commitments outside headline borrowings.

Coverage limits: no live bond quotations, current comprehensive ratings table, quantitative issuer PD model, complete AI-company ranking, or proprietary Morningstar report. The supplied margin/R&D lists were not adopted as verified data. Unverified means evidence is insufficient, not that a claim is necessarily false.

How to audit this report

1. Match the period and units before comparing a number.
2. Recalculate CFO minus cash capex and the cash/debt bridge.
3. Check whether leases or securities have been included.
4. Match each issue term to its exact tranche and pricing date.
5. Refresh current filings and quotations before making an investment decision.
